

What is the normal radiation value of energy storage charging pile

How much energy is stored per unit pile?

Quantitatively, the daily average rate of energy storage per unit pile length reaches about 200 W/m for the case in saturated soil with turbulent flowrate and high-level radiation. This is almost 4 times that in the dry soil. Under low-level radiation, it is about 60 W/m.

Does flow rate affect energy storage during the first charging phase?

By the end of the first charging phase, the rate of energy storage per unit pile length in saturated soil is about 150 W/m higher than that in dry soil. The flowrate seems to have no significant effect on the evolution of the rate of energy storage during the first charging phase, except for cases in saturated soil.

How does solar radiation affect energy storage?

The results showed that under abundant solar radiation, the daily average rate of energy storage per unit pile length increases by about 150 W/m when the soil condition changes from being dry to saturated, with a maximum value of about 200 W/m. As the intensity of solar radiation drops, it becomes the dominant factor.

What is the maximum daily average rate of energy storage?

The maximum daily average rate of energy storage measured is about 200 W/m. A mathematical model of the coupled system was validated against measurements. Energy storage needs to account for the intermittence of solar radiation if solar energy is to be used to answer the heat demands of buildings.

What is the maximum temperature of a solar energy pile?

It indicates that both the inlet and outlet temperature of the energy pile undergo a rapid increase during the first hour. Then they increase quite slowly as the underground storage of solar thermal energy continues. The maximum inlet temperature is about 60 °C.

How to determine the heat exchange capacity of an energy pile?

The heat exchange capacity of an energy pile could be determined from an in situ test (thermal response test) or from an advanced three-dimensional numerical analysis (Ozudogru et al., 2012). Morino and Oka (1994) conducted the first experimental study to assess the heat exchange behaviour of a steel pile equipped with two vertical tubes.

By the end of the one-year operation, its daily average rate of solar energy storage is about 10 W/m less than that of the single energy pile. In addition, the daily average rate of solar energy storage of the corner pile of the 3 × 3 group is also less than that of the corner pile of the 2 × 2 group.
