What is the thermal conductivity of a cell?

If we look at the active layers of a cell the thermal conductivity in the plane of the layers is approximately 10x to 100x that through the planes. This should not be unexpected as the electrodes are made from sheets of aluminium and copper. Two of the best materials for thermal conductivity. These values though have a large range:

What is the best material for thermal conductivity?

Two of the best materials for thermal conductivity. These values though have a large range: 15 to 160 W/mK In-Plane 0.2 to 8 W/mK Through-Plane In the units for thermal conductivity you will see that this is per unit thickness of the material. Closing the distance between the two surfaces means you will improve the thermal conductivity.

What are thermal interface materials?

Thermal Interface Materials The purpose of thermal interface materials (TIM) is to transfer heat between two solid surfaces. In the case of a battery this is normally between the outer surface of the cell case and a cooling plate. Example TIM: fujipoly Sarcon thermal pads

What is the thermal conductivity of aluminium?

The thermal conductivity of aluminium = 236 W/m.K, the thermal conductivity of a typical TIM ~ 2 W/m.K a quite poor thermal conductor. However, no surfaces are flat and the thermal conductivity of air = 0.024 W/m.K a good insulator. Thermal Conductivity of the Active Layers

What is the thermal conductivity of the PCM?

The thermal conductivity of the PCM was measured using a Modified Transient Plane Source sensor from C-Therm. It was found to have a thermal conductivity of 20 W/mK, compared to 2.5 and 0.024 W/mK for potting compounds and air respectively. With this, thermal runaway was instigated using nail penetration. Results and Conclusion

What materials are used in a battery?

Throughout the battery from a single cell to a complete pack there are many different materials. Aluminium, copper, nickel plating etc
