

# What does capacitor split compensation mean

How does a compensation capacitor work?

Here, the compensation capacitor is connected to an internal low impedance node in the first gain stage, which allows indirect feedback of the compensation current from the output node to the internal high-impedance node i.e. the output of the first stage. Figure 1 shows an indirect compensated op-amp using a common-gate stage .

Can a compensation capacitor be replaced with a Miller capacitor?

Figure 2: Operational amplifier with compensation capacitor transformed using Miller's theorem to replace the compensation capacitor with a Miller capacitor at the input and a frequency-dependent current source at the output. (edit: This figure is faulty, as the + and - signs should be switched. There needs to be negative feedback.)

What happens when a capacitor is placed between input and output?

When a capacitor is introduced between the input and output sides of the amplifier with the intention of moving the pole lowest in frequency (usually an input pole) to lower frequencies, pole splitting causes the pole next in frequency (usually an output pole) to move to a higher frequency.

What happens if a capacitor is introduced in an amplifier?

This example shows that introduction of the capacitor referred to as  $C_C$  in the amplifier of Figure 1 has two results: first it causes the lowest frequency pole of the amplifier to move still lower in frequency and second, it causes the higher pole to move higher in frequency.

What is a Miller capacitor?

Miller - Use of a capacitor feeding back around a high-gain, inverting stage. Miller capacitor only Miller capacitor with an unity-gain buffer to block the forward path through the compensation capacitor. Can eliminate the RHP zero. Miller with a nulling resistor.

How does compensation capacitance affect op-amp polarity?

This compensation capacitance creates the desired dominant-pole behavior in the open-loop transfer function of the op-amp. Circuit analysis of this compensation leads to a mathematical observation of "pole splitting"; that as the compensation capacitance is increased, the parasitic poles of the amplifier separate in frequency.
